Abstract. — This text aims at presenting an elementary version of Calabi-Weil infinitesimal rigidity result. It relies on the proof presented in the book by M.S. Raghunatan. The goal is to prove the vanishing of some cohomology group using the Bochner formula and thus to establish such a formula.

Résumé (Rigidité infinitésimale de Calabi-Weil). — Ce texte a pour but de présenter de manière élémentaire la preuve de la rigidité infinitésimale de Calabi-Weil. Il s'appuie sur le livre de M.S. Raghunatan. Il s'agit de prouver l'annulation d'un groupe de cohomologie en utilisant la méthode de Bochner et donc d'établir la formule adéquate.

2000 Mathematics Subject Classification. — 53C24, 53C35, 22E40.
Key words and phrases. — infinitesimal rigidity, Bochner formula, uniform lattice.
We based these lectures on the approach developed by Raghunathan ([Rag]). The reader can also see the original papers by A. Weil (see [We1], [We2]). The text which follows is neither intended to be original nor exhaustive. It aims at presenting in a very elementary way the theory of infinitesimal rigidity as described in [Rag]. A general reference pour a geometric point of view on symmetric spaces is [Ebe], and more detailed bibliographies are provided in [Rag] or [Mar].

Introduction

A trivial example. — The group \( \mathbb{Z} \) can be viewed as a subgroup of the group of translations of the real line \( \mathbb{R} \), and in infinitely many ways. More precisely let \( t \in \mathbb{R} \) and let us call \( T_t \) the translation defined by

\[
T_t(x) = x + t \quad \text{for} \quad x \in \mathbb{R}.
\]

Translations are isometries of the Euclidean structure on \( \mathbb{R} \), so that we can define a family of morphisms

\[
\rho_t : \mathbb{Z} \hookrightarrow \text{Isom}(\mathbb{R})
\]

\[
n \mapsto T_t^n(x \mapsto x + nt).
\]

Such morphisms are called representations of \( \mathbb{Z} \) as isometries of \( \mathbb{R} \). We thus get a deformation of the canonical representation \( \rho_1 \).

This deformation is not trivial in the sense that there does not exist, for \( t \) close to 1, an isometry \( g_t \) of \( \mathbb{R} \) such that

\[
\forall n \in \mathbb{Z}, \quad \rho_t(n) = g_t \rho_1(n) g_t^{-1}.
\]

Another trivial example. — Again \( \mathbb{Z}^2 \) can be viewed as a subgroup of the group of translations of \( \mathbb{R}^2 \), the quotient space being a torus \( \mathbb{R}^2 / \mathbb{Z}^2 \). The translations of \( \mathbb{R}^2 \) are isometries with respect to the usual Euclidean structure.
The orbit of the origin is a lattice in $\mathbb{R}^2$ generated by two vectors which are image of the origin by the two translations associated to the generators $(1, 0)$ and $(0, 1)$ of $\mathbb{Z}^2$.

There is more flexibility here since one can play with the length of these vectors as well as with the angle between them.

The manifold $\mathbb{R}^2/\mathbb{Z}^2$ are endowed with the metrics coming from the Euclidean metric of $\mathbb{R}^2$ and are thus flat riemannian manifolds. The existence of non trivial deformations corresponds to the existence of many non isometric flat tori. The following basis generated by unit length vectors gives rise to

non isometric tori.

Another remark coming from these trivial examples is that all tori are diffeomorphic but nevertheless metrically different.

The purpose of all courses on Rigidity in this school is to exhibit situations where the opposite results occur. Instead of flexibility as above we shall exhibit rigidity: rigidity of deformations (this course), situation in which diffeomorphic manifolds (or homeomorphic) are isometric and more.
1. Deformations and cohomology

A general reference for this chapter is [Br], see also [Rag].

Let $\Gamma$ be a finitely generated group and $G$ a Lie group. We call $R(\Gamma, G)$ the set of homomorphisms of $\Gamma$ in $G$ endowed with the topology of pointwise convergence. Let $\rho_t$, $t > 0$ be a deformation of a representation $\rho_0$, which we assume to be $C^1$.

Let us define, for $\gamma \in \Gamma$,

$$d_{\rho_0}(t, \gamma) = \rho_t(\gamma)\rho_0(\gamma)^{-1}$$

and

$$h_{\rho_0}(\gamma) = \frac{\partial}{\partial t} \bigg|_{t=0} d_{\rho_0}(t, \gamma)$$

d$$_{\rho_0}(t, \gamma)$ is, for each $\gamma \in \Gamma$, a path in $V$.

Now, for $\gamma, \gamma' \in \Gamma$,

$$d_{\rho_0}(t, \gamma\gamma') = \rho_t(\gamma\gamma')\rho_0(\gamma\gamma')^{-1}$$

the inverse being taken in $G$.

$$d_{\rho_0}(t, \gamma\gamma') = \rho_t(\gamma)\rho_t(\gamma')\rho_0(\gamma')^{-1}\rho_0(\gamma)^{-1}$$

and

$$h_{\rho_0}(\gamma\gamma') = h_{\rho_0}(\gamma) + \rho_0(\gamma)h_{\rho_0}(\gamma')\rho_0(\gamma)^{-1}$$

where the second part is $\text{Ad}(\rho_0(\gamma))(h_{\rho_0}(\gamma'))$, so that $h$ satisfies

$$h_{\rho_0}(\gamma\gamma') = h_{\rho_0}(\gamma) + (\text{Ad} \circ \rho_0)(\gamma) \cdot h_{\rho_0}(\gamma').$$

A particular case of deformations, as mentioned before, consists in taking a $C^1$-path $g_t \in G$ with $g_0 = e$ and defining

$$u_t(\gamma) = g_t\rho_0(\gamma)g_t^{-1} \text{ for all } \gamma \in \Gamma.$$  

Then,

$$d_{u_0}(t, \gamma) = g_t\rho_0(\gamma)g_t^{-1}\rho_0(\gamma)^{-1}$$

$$h_{u_0}(\gamma) = X - \rho_0(\gamma)X\rho_0(\gamma)^{-1}$$

$$= X - (\text{Ad} \circ \rho_0)(\gamma) \cdot X$$

where $X = \frac{d}{dt}g_t \bigg|_{t=0} \in \mathfrak{g}$, the Lie algebra of $G$.

We call this last type of deformations, trivial deformations. So that if there exists a non trivial deformation of the representation $\rho_0$, then there
exists a function $h : \Gamma \to G$ satisfying (*) for all $\gamma \in \Gamma$ and not of the type (**).

2. Cohomology of groups

See [Br] for a quite complete description of cohomology of groups.

We consider the elementary case of this theory. Let $V$ be a vector space (an abelian group) on which $\Gamma$ acts, that is, there is a representation $\rho$ of $\Gamma$ in $\text{GL}(V)$. We consider the following complex

$$\cdots \to \Lambda^k(\Gamma, V) \xrightarrow{d} \Lambda^{k+1}(\Gamma, V) \to \cdots$$

where $C^0(\Gamma, V) = V$ and $C^k(\Gamma, V) = \left\{ f : \underbrace{\Gamma \times \cdots \times \Gamma}_{k\text{-times}} \to V \right\}$ and $d$ is given by

$$d_{\rho} f(\gamma_1, \ldots, \gamma_k) = \rho(\gamma_1) f(\gamma_2, \ldots, \gamma_k) + \sum_{i=2}^k (-1)^{i-1} f(\gamma_1, \ldots, \gamma_i \gamma_i^{-1}, \ldots, \gamma_k) + (-1)^k f(\gamma_1, \ldots, \gamma_k^{-1})$$

This is the non homogeneous version of group cohomology. For $k = 0, 1$, we have

i) for $v \in V = C^0(\Gamma, V)$, $dv(\gamma) = \rho(\gamma)v - v$, for all $\gamma \in \Gamma$,

ii) for $f \in C^1(\Gamma, V)$,

$$df(\gamma_1, \gamma_2) = f(\gamma_1) + \rho(\gamma_1)f(\gamma_2) - f(\gamma_1 \gamma_2)$$

for all $\gamma_1, \gamma_2 \in \Gamma$.

A 1-cocycle with value in $\rho$ (or in $V$) is a map

$$f : \Gamma \to V$$

such that, for all $\gamma, \gamma' \in \Gamma$,

$$f(\gamma \gamma') = f(\gamma) + \rho(\gamma)f(\gamma').$$

As usual we define

$$H^1(\Gamma, \rho) = \frac{\text{Ker}\{d : C^1 \to C^2\}}{\text{Im}\{d : C^0 \to C^1\}}.$$
3. Local rigidity

We have seen in section 1 that a nontrivial deformation of a representation gives rise to a non vanishing 1-cocycle. We shall now state that, in certain instances, if the first cohomology group vanishes then the representation is locally rigid. The group $\Gamma$ was supposed to be finitely generated (we can even assume it to have a finite presentation), let $S$ be a finite generating system then one can write $G = F(S)/H$ where $F(S)$ is the free group generated by $S$ and $H$ is the normal subgroup of $F$ constituted by the relations. More precisely if $p : F(S) \longrightarrow \Gamma$ is the natural “projection”, then $H = \text{kernel}(p)$.

Let $S = \{s_1, \ldots, s_N\}$, for $x \in H$ with $x = s_{i_1}^{\varepsilon_1} \cdots s_{i_k}^{\varepsilon_k}$, $s_{i_j} \in S$, we consider the map

$$f_x : \prod_S G = \{h = (g_{s_1}, \ldots, g_{s_N})\} \longrightarrow G$$

$$h \longmapsto g_{s_{i_1}}^{\varepsilon_1} \cdots g_{s_{i_k}}^{\varepsilon_k}$$

and for $\rho \in R(\Gamma, G)$, we define $h_\rho \in \prod S G$ by

$$h_\rho = (\rho(s_1), \ldots, \rho(s_N)),$$

we then have

**Lemma 3.1.** — The map $\varphi : R(\Gamma, G) \rightarrow \prod_S G$, defined by $\varphi(\rho) = h_\rho$, is a bijection between $R(\Gamma, G)$ and $\bigcap_{x \in H} f_x^{-1}(e)$. If $R(\Gamma, G)$ is endowed with the topology of pointwise convergence then $\varphi$ is a homeomorphism onto its image.

This lemma is an easy exercise left to the reader.

If $\Gamma$ is finitely presented, then $H$ is finitely generated and the above intersection can be taken to be finite (by taking $x$ in a generating set for $H$). Furthermore if $G$ is an algebraic group over a field $k$ then $R(\Gamma, G)$ is a variety defined over $k$.

Finally, $G$ acts on $R(\Gamma, G)$ by

$$(g, \rho) \longmapsto gpg^{-1}$$
where $g\rho g^{-1}$ is the morphism

$$
\Gamma \rightarrow G \\
\gamma \mapsto g\rho(\gamma)g^{-1}
$$

**Definition 3.2.** — A representation $\rho_0 \in R(\Gamma, G)$ is locally rigid if the orbit of $\rho_0$ under the action of $G$ is a neighbourhood of $\rho_0$ in $R(\Gamma, G)$.

**Remarks**

i) This definition means that close to $\rho_0$ (in the topology given by a finite generating system) a representation $\rho$ is a trivial deformation of $\rho_0$.

ii) In the introduction we used 1-parameter deformations which are $C^1$; the above definition is more general.

The key result of these lectures is the

**Theorem 3.3 (A. Weil [We3]).** — Let $G \subset \text{GL}(n, \mathbb{C})$ an algebraic group and $\rho_0 \in R(\Gamma, G)$. If $H^1(\Gamma, \text{Ad} \circ \rho_0)$ vanishes then $\rho_0$ is locally rigid.

**Remarks**

i) This is more difficult than the sketch made in section 1. Indeed there we just showed that a $C^1$-deformation is tangent at the origin to a trivial deformation when $H^1(\Gamma, \text{Ad} \circ \rho_0) = 0$. However since $R(\Gamma, G)$ is an algebraic variety one can get the stronger result stated above.

ii) The converse is not true. More precisely, there are examples where not all elements of $H^1(\Gamma, \text{Ad} \circ \rho_0)$ give rise to a deformation. The difficulty is thus that one cannot always “integrate” an infinitesimal non-trivial deformation.

We intend to prove Weil’s local rigidity which is

**Theorem 3.4 (A. Weil [We2]).** — Let $G$ be a connected semi-simple Lie group without compact factor and $\Gamma \subset G$ is an irreducible uniform lattice. If $G$ is not locally isomorphic to $\text{SL}_2(\mathbb{R})$, then $H^1(\Gamma, \text{Ad} \circ i) = 0$.

Here $i : \Gamma \hookrightarrow G$ is the injection of $\Gamma$ into $G$. Let us recall that a lattice in $G$ is a discrete subgroup $\Gamma$ of $G$ such that $G/\Gamma$ has finite volume. If in addition it is compact the lattice is then said to be uniform.
Corollary 3.5. — In this situation \( \Gamma \) is locally rigid.

Remarks
i) We shall restrict our (sketch of) proof to the case when \( G \) is a simple Lie group and thus an algebraic subgroup of some \( \text{GL}(n, \mathbb{C}) \).
ii) The first proof of such a result is due to A. Selberg for the case \( G = \text{SL}(n, \mathbb{R}), \ n \geq 3 \). E. Calabi in an unpublished paper has then proved a similar result for lattices in the hyperbolic space of dimension \( \geq 3 \). The case of hermitian symmetric spaces was first established by E. Calabi and E. Vesentini. The general case is due to A. Weil.
iii) In the non-uniform case the result has been extended by H. Garland ([Ga]) and H. Garland and M.S. Raghunathan ([G-R]). G. Margulis’s results then cover all remaining cases ([Mar]).
iv) One should cite Y. Matsushima ([Mat]) for the use of the Bochner formula and computation of some Betti numbers.

4. Differential geometry

Let \( X \) be a connected and oriented differentiable manifold, which will be compact in the sequel and let \( \Gamma = \pi_1(X) \). The group \( \Gamma \) acts on the universal covering \( \tilde{X} \) of \( X \) by deck transformation. We assume that \( \Gamma \) acts on a finite dimensional vector space \( V \) and denote by \( \rho : \Gamma \rightarrow \text{GL}(V) \) the corresponding representation.

This defines a vector bundle \( E(\rho) \) on \( X \), by the following standard construction: \( \Gamma \) acts on \( \tilde{X} \times V \) by the left action,
\[
\Gamma \times (\tilde{X} \times V) \rightarrow \tilde{X} \times V \\
(\gamma, (\tilde{x}, v)) \mapsto (\gamma \tilde{x}, \rho(\gamma)v)
\]
and
\[
E(\rho) = \tilde{X} \times_\rho V = (\tilde{X} \times V)/\Gamma,
\]
is a vector bundle on \( X \), the projection being given by the projection of \( \tilde{X} \times V \) onto \( \tilde{X} \). This bundle is flat, that is to say that it has a flat connection. This means two equivalent properties:
i) There is a foliation on \( E(\rho) \) transverse to the fibers of \( \pi : E(\rho) \to X \). Lifted to \( \tilde{X} \times V \) the leaf of this foliation through \( (\tilde{x}, v) \) is \( \tilde{X} \times \{ v \} \) while the fiber of \( \pi \) is \( \{ \tilde{x} \} \times V \). This is the geometric point of view on connections.

ii) There is a flat covariant derivative. Precisely a section \( s \) of the bundle can be viewed as an \( \rho \)-equivariant map

\[
\tilde{s} : \tilde{X} \to (\tilde{X} \times \tilde{V})
\]

\[
\tilde{x} \mapsto (\tilde{x}, \varphi(\tilde{x}))
\]

where \( \varphi : \tilde{X} \to \tilde{V} \) satisfies

\[
\forall \gamma \in \Gamma, \quad \varphi(\gamma \tilde{x}) = \rho(\gamma) \varphi(\tilde{x})
\]

Indeed this defines a section by

\[
s([\tilde{x}]) = [(\tilde{x}, \varphi(\tilde{x}))]
\]

where \([\tilde{x}]\) (resp. \([(\tilde{x}, \varphi(\tilde{x}))]\)) then denotes the class of \( \tilde{x} \) (resp. \((\tilde{x}, \varphi(\tilde{x}))\)) for the equivalence relation given by the action of \( \Gamma \). One then has the commutative diagram

\[
\begin{array}{c}
\tilde{X} \times \tilde{V} \quad \xrightarrow{s} \quad E(\rho) \\
\downarrow \quad \tilde{s} \quad \downarrow \pi \\
\tilde{X} \quad \xrightarrow{p} \quad X
\end{array}
\]

**Exercise:** We showed how to get \( s \) from \( \tilde{s} \). Explain how to construct \( \tilde{s} \) from \( s \).

Now let \( U \) be a vector field near \( x \in X \) and \( \tilde{U} \) the pulled back of \( U \) in \( T\tilde{X} \), we define \( D_U s \) through the previous construction using \( \tilde{U} \cdot \varphi \); that is

\[
(\tilde{U} \cdot \varphi)(\tilde{x}) = d_{\tilde{x}} \varphi(\tilde{U})
\]

Here \( p(\tilde{x}) = x \). We remark that, by construction,

\[
\tilde{U}(\gamma \tilde{x}) = d_{\tilde{x}} \gamma(\tilde{U}(\tilde{x}))
\]
then
\[ d_{\gamma \tilde{x}} \varphi [\tilde{U}(\gamma \tilde{x})] = d_{\tilde{x}} (\varphi \circ \gamma)(\tilde{U}(\tilde{x})) = d_{\tilde{x}} (\rho(\gamma) \circ \varphi)(\tilde{U}(\tilde{x})) = \rho(\gamma)(d_{\tilde{x}} \varphi(\tilde{U}(\tilde{x}))) \]

since the action of \( \rho(\gamma) \) on \( V \) is linear. This shows the equivariance of the derivative \( \tilde{U} \cdot \varphi \) which in turn defines the value at \( x \) of a new section denoted by \( (D_U s)(x) \). The operator \( D \) is a covariant derivative, the analytic version of a connection. It is clearly flat, indeed let \( (x_1, \ldots, x_n) \) be a coordinate chart of \( X \) around a point \( x \in X \) and let \( \partial/\partial x_i \) be the canonical vector fields, then, for any section \( s \) defined in a neighbourhood of \( x \),
\[ D_{\partial/\partial x_i} D_{\partial/\partial x_j} s = D_{\partial/\partial x_j} D_{\partial/\partial x_i} s \]

which is the Schwarz lemma, asserting the flatness of \( D \). It is also straightforward to check the flatness in the universal cover since there the connection is just the standard differential.

**Exercise:** Check the above formula.

For a section \( s \), the map
\[ TX \longrightarrow E(\rho) \]
\[ u \longmapsto D_\ast s \]
gives rise to a differential form on \( X \) with values in the bundle \( E(\rho) \); it is thus a section of the bundle \( T^* X \otimes E(\rho) \longrightarrow X \). In general we define a \( k \)-differential form with value in \( E(\rho) \) as being a section of the bundle \( \Lambda^k(X) \otimes E(\rho) \). More precisely such a form is locally a linear combination of terms of the type \( \omega \otimes s \), where \( \omega \) is a real-valued \( k \)-form and \( s \) is a (local) section of \( E(\rho) \). We denote by
\[ \Lambda^k(E) = \{ k \text{-forms with values in } E(\rho) \} . \]

The operator \( D \) allows to define a coboundary operator,
\[ d^D : \Lambda^k(E) \longrightarrow \Lambda^{k+1}(E) \]
by the formula

\[ d^D \omega(U_1, \ldots, U_{k+1}) = \sum_{i=1}^{k+1} (-1)^{i+1} D_{U_i} \omega(U_1, \ldots, \widehat{U_i}, \ldots, U_{k+1}) + \sum_{i<j} (-1)^{i+j} \omega([U_i, U_j], U_1, \ldots, \widehat{U_i}, \ldots, \widehat{U_j}, \ldots, U_{k+1}) \]

where \( \omega \in \Lambda^k(E) \) and \( U_i \) are vector fields on \( X \). One can check that \((d^D)^2 = 0 \) (since \( D \) is flat). It gives rise to a cohomology with values in \( E \). We shall denote by \( H^k(X, E) \) the \( k \)-th cohomology group with values in \( E \).

Another point of view could be to work on \( \tilde{X} \) with equivariant map. More precisely one can consider \( \rho \)-equivariant differential forms on \( \tilde{X} \) with values in \( V \) that is linear combinations of terms such as \( \tilde{\omega} \otimes \varphi \), where \( \tilde{\omega} \) is a real-valued differential form on \( \tilde{X} \) and \( \varphi \) is a \( V \)-valued function on \( \tilde{X} \). This is a modest modification of the classical notion of differential forms with values in \( \mathbb{R} \) or \( \mathbb{C} \). One builds a cohomology denoted by \( H^k(\Gamma, \tilde{X}, \rho) \). It is not difficult, and is left as an exercise, to see that these two cohomologies are isomorphic.

**Exercise**: Prove this assertion. The first step is to define the action of \( \Gamma \) on forms with values in \( V \).

The main result of this section is the following

**Theorem 4.1 (S. Eilenberg, [Eil]).** — It \( \tilde{X} \) is contractible then \( H^*(X, E) \) (and \( H^*(\Gamma, \tilde{X}, \rho) \)) are naturally isomorphic to \( H^*(\Gamma, \rho) \).

In particular, one has \( H^1(\Gamma, \rho) \cong H^1(X, E) \). This opens the possibilities of using all the differential geometric techniques in order to prove that \( H^1(\Gamma, \rho) = 0 \) and thus the local rigidity of certain representations.

**Remarks**

i) A contractible space is a topological space such that the identity is homotopic to a constant map. The symmetric spaces of non positive curvature are contractible.

ii) The above theorem is not difficult to understand in certain easy situations. Let us assume that \( \tilde{X} \) is non positively curved (a real hyperbolic space for example) and let \( \omega \) be a 1-form on \( \tilde{X} \) with values in \( V \).
and $\rho$-equivariant. We fix an origin $x_0 \in \tilde{X}$ and define, for $\gamma \in \Gamma$:

$$f(\gamma) = \int_{x_0}^{\gamma x_0} \omega = \text{integral of } \omega \text{ on the (unique) geodesic between } x_0 \text{ and } \gamma x_0.$$ 

**Lemma 4.2.** — If $\omega$ is closed then $f$ is a 1-cocycle.

**Proof.** — Since $\omega$ is closed, one has

$$f(\gamma \gamma') = \int_{x_0}^{\gamma \gamma' x_0} \omega = \int_{x_0}^{\gamma x_0} \omega + \int_{\gamma x_0}^{\gamma' x_0} \omega$$

now

$$\int_{\gamma x_0}^{\gamma' x_0} \omega = \int_{x_0}^{\gamma' x_0} \gamma^* \omega = \int_{x_0}^{\gamma' x_0} \rho(\gamma)(\omega) = \rho(\gamma) \left( \int_{x_0}^{\gamma' x_0} \omega \right)$$

by linearity of the action $\rho(\gamma)$. Here we used the equivariance of $\omega$ which reads, for $u \in T_x M$,

$$(\gamma^* \omega)_x(u) = \omega_{\gamma x}(d_x \gamma(u)) = \rho(\gamma)(\omega_x(u)).$$

We thus proved

$$f(\gamma \gamma') = f(\gamma) + \rho(\gamma) f(\gamma')$$

which is exactly

$$df \equiv 0.$$  

One can extend this construction to arbitrary forms and show that the correspondence yields an isomorphism between the two cohomologies.

**Exercise:** Just do it!
5. Hodge theory

The reader can learn the Hodge theory for real-valued forms in [Wa], for example.

If $X$ is an oriented Riemannian manifold then the scalar product (the metric) extends to a scalar product for $k$-forms. More precisely let $\omega$ and $\eta$ be two real-valued $k$-forms and let $\{e_i\}_{i=1,\ldots,n}$ be an orthonormal basis of $T_x X$, then the scalar product at $x$ is defined by

$$(\omega, \eta)(x) = \sum_{i_1 < i_2 < \cdots < i_k} \omega(e_{i_1}, \ldots, e_{i_k}) \eta(e_{i_1}, \ldots, e_{i_k}).$$

We may then talk about orthonormal basis of real-valued $k$-forms.

We now assume that $E(\rho) \to X$ is a metric bundle, i.e. the fiber above $x$ carries a Euclidean structure $g_x$ depending smoothly on $x \in X$.

Such a metric gives a (musical) isomorphism:

$$\flat : E(\rho)_x \to E(\rho)^*_x$$

defined by

$$\flat^\flat(u) = g_x(u, v).$$

This naturally extends to a pairing

$$\flat : \Lambda^k(E) \to \Lambda^k(E^*)$$

by $(\omega \cdot u)^\flat = \omega u^\flat$ if $\omega$ is a real-valued form and $u \in E(\rho)$. On a coordinate open set on $X$, let $\alpha_1, \ldots, \alpha_n$ be real-valued 1-forms which are a local basis of $T^* X$. Then, on this set, for $\xi \in \Lambda^k(E)$, one can write

$$\xi = \sum_{i_1 < \cdots < i_k} u_{i_1 \ldots i_k} \alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k}$$

where $u_{i_1 \ldots i_k}$ are smooth sections of $E(\rho)$ (or $E(\rho)^*$). Now, if $\eta \in \Lambda^l(E^*)$, we define

$$\xi \wedge \eta = \sum_{i_1 < \cdots < i_k} v_{j_1 \ldots j_\ell} (u_{i_1 \ldots i_k}) \alpha_{j_1} \wedge \cdots \wedge \alpha_{j_\ell} \wedge \alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k}.$$

It is a scalar $k + \ell$-form.

The Hodge-star operator is then defined by

$$* : \Lambda^k(E) \to \Lambda^{n-k}(E)$$

$$*\xi = \sum u_{i_1 \ldots i_k} * (\alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k}).$$
We thus have to define the ∗-operator for real-valued forms;

\[ * : \Lambda^k(X) \rightarrow \Lambda^{n-k}(X) \]

for \( \alpha \) and \( \beta \in \Lambda^k(X) \), \( \alpha \wedge \ast \beta = (\alpha, \beta)\mathrm{dvol} \);

where \((\cdot, \cdot)\) is the scalar product on \( k \)-forms on \( X \). If \( \{\alpha_1, \ldots, \alpha_n\} \) is a positive orthonormal basis of real valued 1-forms at \( x \in X \), then

\[ *(\alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k}) = \alpha_{j_1} \wedge \cdots \wedge \alpha_{j_l}, \ k + \ell = n \]

where \( (j_1, \ldots, j_l) \) are such that

\[ \alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k} \wedge \alpha_{j_1} \wedge \cdots \wedge \alpha_{j_l} = \alpha_1 \wedge \cdots \wedge \alpha_n. \]

The following properties are easily checked

i) \( *\ast \xi = (-1)^{k(n-k)}\xi \) for \( \xi \in \Lambda^k(E) \)

ii) for \( \xi, \eta \in \Lambda^k(E) \), \( \xi = \sum u_{i_1 \cdots i_k} \alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k} \) and \( \eta = \sum v_{i_1 \cdots i_k} \alpha_{i_1} \wedge \cdots \wedge \alpha_{i_k} \) where \( \{\alpha_i\}_{i=1, \ldots, n} \) is a (local) orthonormal basis of real-valued 1-forms we set

\[ (\xi, \eta) = \sum_{i_1 < \cdots < i_k} g_x(u_{i_1 \cdots i_k}, v_{i_1 \cdots i_k}) \]

and we have

\[ \xi \wedge (\ast \eta)^\flat = (\xi, \eta)\mathrm{dvol}. \]

We can also define a global scalar product

\[ \langle \xi, \eta \rangle = \int_X (\eta, \xi)\mathrm{dvol} = \int_X \eta \wedge (\ast \xi)^\flat \]

when the integral makes sense, for example, when one of the forms is compactly supported.

With the help of these structures we shall construct some natural differential operators.

**Definition 5.1.** — The codifferential \( \delta^D : \Lambda^{k+1}(E) \rightarrow \Lambda^k(E) \) is the operator

\[ \delta^D \xi = (-1)^{k(n-k)+k+1} \# (\ast d^D \ast (\xi^\flat)) \]

where \( \# = (\flat)^{-1}. \)

It is straightforward to check the following result,

**Proposition 5.2.** — \( \langle d^D \alpha, \beta \rangle = \langle \alpha, \delta^D \beta \rangle \) for \( \alpha \in \Lambda^k(E) \), \( \beta \in \Lambda^{k+1}(E) \) and one of them is compactly supported.
In other words $\delta^D$ is the formal adjoint of $d^D$.

**Definition 5.3.** — We define the Hodge Laplacian acting on $E$-valued forms by

$$\Delta^D = d^D \delta^D + \delta^D d^D = d^D (d^D)^* + (d^D)^*(d^D)$$

The operator $\Delta^D$ preserves the degree of forms.

**Proposition 5.4.** — i) $\Delta^D$ is formally self-adjoint, that is

$$\langle \Delta^D \xi, \eta \rangle = \langle \xi, \Delta^D \eta \rangle$$

for $\xi, \eta \in \Lambda^k(E)$ and one of them is compactly supported.

ii) With the same notations

$$\langle \Delta^D \xi, \eta \rangle = \langle d^D \xi, d^D \eta \rangle + \langle \delta^D \xi, \delta^D \eta \rangle .$$

**Definition 5.5.** — A form $\xi \in \Lambda^k(E)$ is said to be harmonic when $\Delta^D \xi = 0$, which is equivalent to

$$d^D \xi = \delta^D \xi = 0,$$

When $X$ is compact or $\xi$ is compactly supported.

The main results of the Hodge theory is (see [Wa]):

**Theorem 5.6.** — If $X$ is compact without boundary, every closed form $\xi \in \Lambda^k(E)$ (i.e., $d^D \xi = 0$) is cohomologous to a unique harmonic form. Thus $H^k(X, E)$ is isomorphic to the vector space of $k$-harmonic $E$-valued forms.

**Corollary 5.7.** — Let $X$ be compact, if there exists $c > 0$ such that, for all $\xi \in \Lambda^k(E)$,

$$\langle \Delta^D \xi, \xi \rangle \geq c \lVert \xi \rVert^2$$

then $H^k(X, E) = 0$.

The goal is now to compute, in the case under consideration, $d^D$, $\delta^D$ and $\Delta^D$ acting on $k$-forms. We shall show that

$$\Delta^D \xi = \overline{\Delta} \xi + Q(\xi)$$

where $\overline{\Delta}$ is a nonnegative operator and $Q$ is an endomorphism (it does not differentiate $\xi$) which is positive.
6. Applications I

Let $G$ be a semi-simple connected Lie group without compact factor and $\Gamma$ a uniform lattice. Let $K$ be maximal compact subgroup, then $\tilde{X} = G/K$ is the symmetric space defined by $G$ which is simply connected of non positive curvature and thus contractible by Hadamard-Cartan’s theorem (for example).

We shall make the assumption that the representation
\[ \rho : \Gamma \to GL(V) \]
is the restriction to $\Gamma$ of a morphism, called $\rho$ again,
\[ \rho : G \to GL(V) . \]

**Remark 6.1.** — This is the case in the situation of Calabi-Weil’s rigidity since we have to consider
\[ \rho = \text{Ad} \circ i , \quad V = g \]
where $i$ is the injection of $\Gamma$ into $G$. The representation $\rho$ is thus the restriction to $\Gamma$ of Ad.

We “extend” $\rho$ to the Lie algebra $g$. Indeed if $Y \in g$ and $\varphi_t$ is the one-parameter group generated by $Y$, we then set
\[ v \in V , \quad \rho(Y)v = \frac{d}{dt} \bigg|_{t=0} \rho(\varphi_t)v = \left. \rho(\varphi_t)v \right|_{t=0} . \]

Let us consider the following diagram
\[ \begin{array}{ccc}
E(\rho) & \leftarrow & \tilde{X} \times V \\
\downarrow & & \downarrow \\
X & \leftarrow & \tilde{X} \leftarrow p \leftarrow G \\
\end{array} \]

We now call $p$ the projection of $G$ onto $\tilde{X}$. $E(\rho)$ is the quotient of $G \times V$ by the following action of $K \times \Gamma$
\[ (k, \gamma) \cdot (g, v) = (\gamma gk, \rho(\gamma)v) . \]

We lift the forms from $\tilde{X}$ to $G$. Let $\omega$ be a $k$-form on $\tilde{X}$ with values in $V$ and which is $\rho$-equivariant, i.e. $\omega$ satisfies
\[ \gamma^*\omega = \rho(\gamma) \circ \omega . \]
We pull it back to $G$ as follows:

$$\omega_g = \rho(g)^{-1}(\rho^* \omega_{p(g)}) .$$

The aim is to make the computations on $G$ and use the underlying algebra. The previous formula means that if $Z_1, \ldots, Z_k$ are vector fields near $g$ and $\overline{Z}_i = dp(Z_i)$ then

$$\omega_g(Z_1, \ldots, Z_k) = \rho(g)^{-1} \omega_{p(g)}(\overline{Z}_1, \ldots, \overline{Z}_k) .$$

The space of such forms is denoted $\Lambda^k(\Gamma, G, K, \rho)$.

**Proposition 6.2.** — If $\omega \in \Lambda^k(\Gamma, G, K, \rho)$ then

i) $\gamma^* \omega = \omega$, for all $\gamma \in \Gamma$.

ii) $R_k(\omega) = \rho(k)^{-1} \omega$, for all $k \in K$, where $R_k$ denotes the right multiplication by $k \in K$.

iii) $i(Y) \omega = 0$ for all $Y \in \mathfrak{k}$, where $\mathfrak{k}$ is the Lie algebra of $K$.

**Sketch of proof.** — iii) $i(Y) \omega$ is the inner product of $\omega$ by $Y$. With the above notations

$$i(Y)\omega(Z_1, \ldots, Z_{k-1}) = \omega(Y, Z_1, \ldots, Z_{k-1}) = 0$$

since $p_\ast(Y) = dp(Y) = 0$.

i) Let us check this too, one has

$$(\gamma^* \omega)_g(Z_1, \ldots, Z_k) = \omega_{\gamma g}(d\gamma(Z_1), \ldots, d\gamma(Z_k))$$

$$= \rho(\gamma g)^{-1} \left( \overline{\omega_{p(\gamma g)}}(d\gamma(\overline{Z}_1), \ldots, d\gamma(\overline{Z}_k)) \right)$$

now $p(\gamma g) = \gamma p(g)$ by definition of the action on $G/K$ and thus $d\gamma(\overline{Z}_i) = d\gamma(Z_i)$. We then have

$$(\gamma^* \omega)_g(Z_1, \ldots, Z_k) = \rho(g)^{-1} \rho(\gamma)^{-1} \left( \overline{\omega_{p(g)}}(d\gamma(\overline{Z}_1), \ldots, d\gamma(\overline{Z}_k)) \right)$$

$$= \rho(g)^{-1} \rho(\gamma)^{-1} \left( \gamma^* \overline{\omega_{p(g)}}(\overline{Z}_1, \ldots, \overline{Z}_k) \right)$$

$$= \rho(g)^{-1} \overline{\omega_{p(g)}}(\overline{Z}_1, \ldots, \overline{Z}_k)$$

ii) This is left to the reader. \hfill $\square$

Being invariant by $\Gamma$ allows to view these forms as $k$-forms on $\Gamma \setminus G$ with values in $V$ satisfying ii) and iii). Now if we call $\Lambda^k(\Gamma, \tilde{X}, p)$ the
ρ-equivariant $k$-forms on $\tilde{X}$ with values in $V$, then one has the following diagram

$$
\begin{array}{ccc}
\Lambda^k(\Gamma, X, \rho) & \xrightarrow{d^\rho} & \Lambda^{k+1}(\Gamma, X, \rho) \\
\uparrow & & \uparrow \\
\Lambda^k(\Gamma, G, K, \rho) & \xrightarrow{d\rho} & \Lambda^{k+1}(\Gamma, G, K, \rho)
\end{array}
$$

This gives defines a differential operator $d\rho$. The isomorphisms

$$
\Lambda^k(\Gamma, X, \rho) \simeq \Lambda^k(\Gamma, G, K, \rho)
$$

are easy to understand.

**Proposition 6.3.** — For $\omega \in \Lambda^k(\Gamma, G, K, \rho)$ and $Z_1, \ldots, Z_{k+1} \in \mathfrak{g}$

$$
d_{\rho}(\omega)(Z_1, \ldots, Z_{k+1}) = \sum_{s=1}^k (-1)^{s+1}(Z_s + \rho(Z_s))\omega(Z_1, \ldots, \hat{Z}_s, \ldots, Z_{k+1})$$

$$+ \sum_{s<t} (-1)^{s+t}\omega([Z_s, Z_t], Z_1, \ldots, \hat{Z}_s, \ldots, \hat{Z}_t, \ldots, Z_{k+1})
$$

**Remark 6.4.** — $Z_s + \rho(Z_s)$ consists of a derivation by $Z_s$ and an operator $\rho(Z_s) \in \text{GL}(V)$ applied to the vector $\omega(Z_1, \ldots, \hat{Z}_s, \ldots, Z_{k+1}) \in V$.

**Sketch of proof.** — With the previous notations

$$(d_{\rho}(\omega))_g = \rho(g)^{-1}(p^*(d\omega))_g .$$

When one differentiates expression of the type $\rho(g)^{-1}p^*(\eta)$ one differentiates $p^*(\eta)$ but also $\rho^{-1}(g)$; In fact

$$d\omega = d(\rho^{-1}) \wedge p^*(\overline{\omega}) + \rho^{-1}d(p^*\overline{\omega})$$

where here $d\omega$ denotes the differential on $G$. This condensed notation means that the GL(V) valued 1-form $d(\rho^{-1})$ is paired with the $V$-valued form $p^*(\overline{\omega})$ by exterior product on the “form” part and by the action of GL(V) on $V$ for the “vector” part. Thus

$$d_{\rho}(\omega) = d\omega - d(\rho^{-1}) \wedge p^*(\overline{\omega})$$

since $p^*(d\omega) = d(p^*\omega)$. It remains to compute $d_g\rho^{-1}(Y)$ for $Y \in \mathfrak{g}$. Let $\varphi_t$ the one-parameter group generated by $Y$, then

$$\frac{d}{dt} \bigg|_{t=0} \rho^{-1}(\varphi_t) = \frac{d}{dt} \bigg|_{t=0} \left( \rho^{-1}(g\varphi_t) \right) \rho^{-1}(g) = -\rho(Y)\rho^{-1}(g) .$$
We thus have
\[ d_{\rho}\omega = d\omega + \rho(\cdot) \wedge \omega. \]

Let us apply these remarks to the case of a 1-form \( \omega \). Let \( Z_1, Z_2 \in g \)
\[
d_{\rho}(Z_1, Z_2) = Z_1 \cdot \omega(Z_2) - Z_2 \cdot \omega(Z_1) - \omega([Z_1, Z_2])
+ \rho(Z_1)\omega(Z_2) - \rho(Z_2)\omega(Z_1)
= (Z_1 + \rho(Z_1))\omega(Z_2) - (Z_2 + \rho(Z_2))\omega(Z_1) - \omega([Z_1, Z_2])
\]
which is the desired formula. The other cases are left to the reader. \[\qed\]

**Remark 6.5.** — It is worth noticing that we never used the semi-simplicity of \( G \). We just need at this stage \( G \) to be a connected Lie group, \( K \) to be a closed compact subgroup such that \( G/K \) is contractible and \( \Gamma \) a discrete subgroup. These computations can be used to show that the cohomology \( H^k(\Gamma, \rho) \) when \( G \) is solvable or nilpotent can be computed in terms of the cohomology of the Lie algebra \( g \) of \( G \).

### 7. Applications II: Semi-simple groups

In order to simplify the exposition we shall restrict ourselves to the case when \( G \) is a simple group. For the general case the reader is referred to [Rag].

We recall that, from the previous section, we are led to study \( k \)-forms on the compact space \( \Gamma \setminus G \) with values in a finite dimensional vector space \( V \) and satisfying the two conditions

a) \( \forall k \in K, R_k^*\omega = \rho(k)^{-1}\omega \).

b) \( \forall Y \in \mathfrak{k}, i(Y)\omega = 0 \).

We shall need to integrate on \( \Gamma \setminus G \), so we choose a bi-invariant measure \( \mu \) (Haar measure) on \( G \), which exists by uni-modularity of semi-simple groups. Now the Lie algebra of \( G \) decomposes
\[ g = \mathfrak{p} \oplus \mathfrak{k} \]
with the property \([\mathfrak{p},\mathfrak{p}] \subset \mathfrak{k}\) (see P. Paradan’s lectures).

The forms are multiplied by \( \rho(k)^{-1} \) when we right-translate them by \( k \in K \). So in order to have a metric structure on \( V \) which descends to a Euclidean structure on \( V \)-valued forms on \( \widetilde{X} \) we need to choose it invariant by \( \rho(K) \). In fact one can do better.
Lemma 7.1 (see [Rag], section 1.5). — Let $\rho$ be a finite dimensional representation of $G$ on a vector space $V$ (over $\mathbb{R}$). Then there exists a Euclidean scalar product $(\cdot, \cdot)_V$ on $V$ with respect to which

i) $\rho(k)$ is orthogonal, $\forall k \in K$.

ii) $\rho(Y)$ is symmetric, $\forall Y \in \mathfrak{p}$.

Exercise: Describe the metric structure $g_x$ on the fiber $E(\rho)_x$ of $E(\rho) \to X$, for $x \in X$.

For $Z \in \mathfrak{g}$ we write $Z = Y + V$ with $Y \in \mathfrak{p}$ and $V \in \mathfrak{k}$, then a $k$-form as above is completely determined by its values on $\mathfrak{p}$ thanks to $b)$. Let us choose an orthonormal basis of $\mathfrak{p}$ denoted $\{Y_1, \ldots, Y_n\}$ where $n = \dim \tilde{X} = \dim \mathfrak{p}$.

A form $\omega \in \Lambda^k(\Gamma, G, K, \rho)$ is completely determined by the functions,

$$\omega_{i_1, \ldots, i_k} = \omega(Y_{i_1}, \ldots, Y_{i_k}) ,$$

and the global scalar product of two $k$-forms $\xi$ and $\eta$ is given by

$$\langle \xi, \eta \rangle = \sum_{i_1 < \cdots < i_k} \int_{G/\Gamma} (\xi_{i_1 \ldots i_k}, \eta_{i_1 \ldots i_k})_V \, d\mu .$$

The following equalities are then consequences of the invariance of $\mu$ and Stoke’s formula (precisely the divergence formula). For $Z \in \mathfrak{g}$ and $f, f_1$ and $f_2$ smooth functions on $\Gamma \setminus G$, one has

$$\int_{G/\Gamma} Z \cdot f \, d\mu = 0 \quad \text{and} \quad \int_{G/\Gamma} (Z \cdot f_1) f_2 \, d\mu = - \int_{G/\Gamma} f_1 (Z \cdot f_2) \, d\mu .$$

These will be used to do the necessary integration by parts in order to compute the adjoint of $d_\rho$.

Proposition 7.2. — Let $\omega \in \Lambda^k(\Gamma, G, K, \rho)$ then, if $k > 0$,

$$(\delta_\rho \omega)_{i_1 \cdots i_{k-1}} = - \sum_{s=1}^n (Y_s - \rho(Y_s))^s \omega_{s i_1 \cdots i_{k-1}}$$

and $\delta_\rho \omega = 0$, if $k = 0$.

Sketch of proof: — $-Y_s$ is the adjoint of $Y_s$ and $\rho(Y_s)$ is self-adjoint (symmetric) by our choice of $(\cdot, \cdot)_V$.

Let us look at two easy cases
1) If $\omega$ is a 1-form, $\delta_\rho \omega$ is then a $V$-valued function. Let $\eta$ be a $V$-valued function, then

$$\langle \delta_\rho, \eta \rangle = \int_{\Gamma \setminus G} \left( - \sum_{s=1}^{n} (Y_s - \rho(Y_s)) \omega(Y_s), \eta \right)_V d\mu$$

which is the desired formula.

2) If $\omega$ is a 2-form, $\delta_\rho \omega$ is a 1-form. Let $\eta$ be another 1-form

$$\langle \delta_\rho, \eta \rangle = \int_{\Gamma \setminus G} \left( \sum_{i=1}^{n} \sum_{s=1}^{n} ((Y_s - \rho(Y_s)) \omega(Y_s, Y_i), \eta(Y_i))_V d\mu \right.$$

$$\langle \omega, d_\rho \eta \rangle = \int_{\Gamma \setminus G} \left( \omega(Y_s, Y_i), (Y_s + \rho(Y_s)) \eta(Y_i) - (Y_i + \rho(Y_i)) \eta(Y_s) \right)_V d\mu$$

In this proof we used the following fact: If $Z_i = Y_i + V_i$ where $Y_i \in p$ and $V_i \in k$, then $d_\rho \omega(Z_1, \ldots, Z_k) = d_\rho \omega(Y_1, \ldots, Y_k)$ for $\omega \in \Lambda^{k-1}(\Gamma, G, K, \rho)$. Indeed in the computation of $d_\rho \omega$ appears terms of the form

$$\omega \left( [Y_s, Y_i], Y_1, \ldots, \hat{Y}_s, \ldots, \hat{Y}_t, \ldots, Y_k \right)$$

which vanish since $[Y_s, Y_i] \in k$.

We can then compute the associated Laplacian $\Delta_\rho = d_\rho \delta_\rho + \delta_\rho d_\rho$.

**Proposition 7.3.** — For $\omega \in \Lambda^k(\Gamma, G, K, \rho)$

$$\langle \Delta_\rho \omega, Y_{i_1}, \ldots, Y_{i_k} \rangle = \sum_{j=1}^{n} \left( -Y_j^2 + \rho(Y_j)^2 \right) \omega_{i_1 \ldots i_k}$$

$$+ \sum_{j=1}^{n} \sum_{s=1}^{k} (-1)^{s+1} \left( -[Y_{i_s}, Y_j] + \rho([Y_{i_s}, Y_j]) \right) \omega_{j_1 \ldots i_s \ldots i_p}.$$
Proof. — It is a straightforward computation. Let us look at the elementary case \( k = 0 \) where \( \Delta_{\rho}\omega = \delta_{\rho}d_{\rho}\omega \).

\[
\Delta_{\rho}\omega = -\sum_{j=1}^{n} (Y_j - \rho(Y_j)) d_{\rho}\omega(Y_j)
\]

\[
= -\sum_{j=1}^{n} (Y_j - \rho(Y_j)) (Y_j + \rho(Y_j))\omega.
\]

Here there is only one term in the sum defining \( d_{\rho} \) since \( \omega \) is a \( V \)-valued function on \( \Gamma \setminus G \).

Let us recall that \( \rho(Y_j) \) is a matrix which is constant, i.e. it does not depend on \( g \in G \), thus

\[
Y_j \cdot \rho(Y_j) \omega = \rho(Y_j)(Y_j \cdot \omega)
\]

and

\[
\Delta_{\rho}\omega = -\sum_{j=1}^{n} Y_j^2 \omega + \sum_{j=1}^{n} \rho(Y_j)^2\omega.
\]

In the other degrees, expressions of the form

\[
(Y_j + \rho(Y_j))(Y_s - \rho(Y_s))
\]

appear and yield the commutators in the above formula. \( \square \)

Now, \( \Delta_{\rho} \) can be decomposed in the sum of two operators

\[
\Delta_{\rho} = \Delta_D + H_{\rho}
\]

where

\[
(\Delta_D\omega)_{i_1 \cdots i_p} = \sum_{j=1}^{n} -Y_j^2 \omega_{i_1 \cdots i_k} - \sum_{j=1}^{n} \sum_{s=1}^{k} (-1)^{s+1}[Y_{i_s}, Y_j]\omega_{j i_1 \cdots i_s \cdots i_k}
\]

and

\[
(H_{\rho}\omega)_{i_1 \cdots i_p} = \text{same formula with derivatives by } Y \text{ replaced by the operator } \rho(Y) \text{ for } Y \in \mathfrak{p}.
\]

Even better, there exist two operators \( D_{\rho} \) and \( T_{\rho} \) such that

\[
\Delta_D = D_{\rho}^*D_{\rho} + D_{\rho}D_{\rho}^* \text{ and } H_{\rho} = T_{\rho}^*T_{\rho} + T_{\rho}T_{\rho}^*
\]

where \( D_{\rho}^* \) is the adjoint of the differential operator \( D_{\rho} \), i.e.

\[
\langle D_{\rho}\xi, \eta \rangle = \langle \xi, D_{\rho}^*\eta \rangle \text{ for } \xi \in \Lambda^k \text{ and } \eta \in \Lambda^{k+1}
\]
and $T^*_\rho$ is the pointwise adjoint of $T_\rho$, i.e.

$$(T_\rho \xi, \eta)_V = (\xi, T^*_\rho \eta)_V .$$

More precisely

$$(D_\rho \xi)_{i_1 \cdots i_{k+1}} = \sum_{s=1}^{k+1} (-1)^{s+1} Y_{i_s} \cdot \xi_{i_1 \cdots i_s \cdots i_{k+1}}$$

$$(D^*_\rho \xi)_{i_1 \cdots i_k} = \sum_{s=1}^{n} (-Y_s) \xi_{si_1 \cdots i_{k-1}}$$

$$(T_\rho \xi)_{i_1 \cdots i_{k+1}} = \sum_{s=1}^{k+1} (-1)^{s+1} \rho(Y_{i_s}) \xi_{i_1 \cdots i_s \cdots i_{k+1}}$$

$$(T^*_\rho \xi)_{i_1 \cdots i_k} = \sum_{s=1}^{n} \rho(Y_s) \xi_{si_1 \cdots i_{k-1}} .$$

These remarks lead to

$$\langle \Delta_\rho \omega, \omega \rangle = \langle \Delta D \omega, \omega \rangle + \langle H_\rho \omega, \omega \rangle$$

for $\omega \in \Lambda^k(\Gamma, G, K, \rho)$, and both operators $\Delta D$ and $H_\rho$ are non-negative.

Let us define

$$\mathcal{Q}_\rho^k(\omega) = \langle H_\rho \omega, \omega \rangle$$

which is a quadratic form on $\Lambda^k(\Gamma, G, K, \rho)$. We aim at showing that it is positive and bounded below.

It is worth noticing that

Exercise: Show that $H_\rho$ does not depend on the choice of the basis of $p$.

The $k$-forms $\omega$ of $\Lambda^k(\Gamma, G, K, \pi)$ are horizontal with respect to the fibration $G \rightarrow \tilde{X}$ thanks to the property b) above.

Let us point out the following two facts

i) $H_\rho$ is a constant operator. Indeed it does not depend on $g \in G$ since it involves expression of the type $\rho(Y)$ for $Y \in p$.

ii) The above remark says that a $k$-form $\omega \in \Lambda^k(\Gamma, G, K, \rho)$ can be viewed as a $k$-linear map, called $\omega$ again

$$\omega : \Lambda^k p \longrightarrow V$$

so we can consider $\omega$ as being an element of $\text{Hom}(\Lambda^k p, V)$. 
Let us now define
\[ Q^1_\rho(\omega) = (H^1_\rho(\omega), \omega) \]
for \( \omega \in \text{Hom}(p, V) \).

**Proposition 7.4.** — If \( Q^1_\rho \) is positive definite on \( \text{Hom}(p, V) \) then there exists \( c > 0 \) such that for all \( \xi \in \Lambda^1(\Gamma, G, K, \rho) \) one has \( \langle \Delta_\rho \xi, \xi \rangle \geq c \| \xi \|^2 \).

**Corollary 7.5.** — \( H^1(\Gamma, \rho) = 0 \).

We now specify the situation to the case under consideration; precisely, \( \rho = \text{Ad} \) and \( V = g \). The canonical metric on \( g \) satisfies the properties required, namely
\[ i) \quad \text{Ad}(k) \text{ is orthogonal, } \forall k \in K. \]
\[ ii) \quad \text{ad}(Y) \text{ is symmetric for all } Y \in p. \]
Notice that the extension of \( \text{Ad} \) to the Lie algebra is \( \text{ad} \).

We thus have to study \( Q^1_{\text{Ad}} \) on the space
\[ \text{Hom}(p, g) \simeq \text{Hom}(p, \mathfrak{t}) \oplus \text{Hom}(p, g). \]
If \( \omega \in \text{Hom}(p, g) \), then we compute
\[ Q^1_{\text{Ad}}(\omega) = \sum_{i=1}^n \left( \sum_{j=1}^n \text{ad}(Y_j)^2(\omega(Y_i)) + \sum_{j=1}^n \text{ad}([Y_i, Y_j])\omega(Y_j), \omega(T_i) \right)_{g}. \]

Now the subspaces \( p \) and \( \mathfrak{t} \) of \( g \) are \( \text{ad}(\mathfrak{t}) \)-invariant; therefore if we write \( \omega = \omega_p + \omega_\mathfrak{t}, \omega_p \in \text{Hom}(p, p) \) and \( \omega_\mathfrak{t} \in \text{Hom}(p, \mathfrak{t}) \), they satisfy the same conditions, namely
\[ i) \quad \forall X \in \mathfrak{t}, 0 = \omega(X) = i_X \omega = \omega_p(X) + \omega_\mathfrak{t}(X) \text{ implies that } \omega_p(X) = 0 \text{ and } \omega_\mathfrak{t}(X) = 0. \]
\[ ii) \quad R^*_k \omega = \text{ad}(k^{-1})\omega_p + \text{ad}(k^{-1})\omega_\mathfrak{t} \text{ for all } k \in K. \]

Furthermore, let us recall that
\[ Q^1_{\text{Ad}}(\omega) = (H^1_{\text{Ad}}(\omega), \omega). \]

**Lemma 7.6.** — \( H^1_{\text{Ad}} \) leaves \( \text{Hom}(p, p) \) and \( \text{Hom}(p, \mathfrak{t}) \) stable and moreover these two sub-spaces are orthogonal for the canonical scalar product on \( \text{Hom}(p, g) \).
Proof. —  i) Let $\omega \in \text{Hom}(p, p)$, then

$$H^1_{\text{Ad}}\omega(Y_i) = \sum_{j=1}^n \text{ad}(Y_j)^2\omega(Y_i) + \sum_{j=1}^n \text{ad}([Y_i, Y_j])\omega(Y_j)$$

is in $p$ for all $Y_i$.

ii) Similarly $H^1_{\text{Ad}}\omega \in \text{Hom}(p, \mathfrak{t})$ when $\omega \in \text{Hom}(p, \mathfrak{t})$.

iii) If $\zeta \in \text{Hom}(p, p)$ and $\beta \in \text{Hom}(p, \mathfrak{t})$ then

$$(\alpha, \beta) = \sum_{i=1}^n (\alpha(Y_i), \beta(Y_j))_g = 0$$

since $p$ and $\mathfrak{t}$ are orthogonal.

Consequently it suffices to study $Q^1_{\text{Ad}}$ on each space.

Remark 7.7. — We shall leave aside the case $\text{Hom}(p, \mathfrak{t})$ which does not contain any information. Furthermore $Q^1_{\text{Ad}}$ is positive on this space without any restriction on the group (see [Rag]). Let us consider $\text{Hom}(p, p)$. Any $\omega$ in this space can be decomposed in

$$\omega = \omega_S + \omega_A$$

where $\omega_S$ is the symmetric part of the endomorphism $\omega$ and $\omega_A$ the skew-symmetric part.

Lemma 7.8. — This decomposition is again stable by $H^1_{\text{Ad}}$ and the two subspaces are orthogonal.

It is thus sufficient to study the two cases separately. Again we shall leave aside the case when $\omega$ is skew-symmetric since $Q^1_{\text{Ad}}$ is positive on this space without any restriction on $G$ (see [Rag]).

Let $\omega \in \text{Hom}(p, p)$ be a symmetric endomorphism. We want to show that if $(H^1_{\text{Ad}}\omega, \omega) = 0$ then $\omega = 0$. Let us recall that

$$H^1_{\text{Ad}} = T^1_{\text{Ad}}(T^1_{\text{Ad}})^* + (T^1_{\text{Ad}})^*T^1_{\text{Ad}}.$$

Thus if $(H^1_{\text{Ad}}\omega, \omega) = 0$ then $T^1_{\text{Ad}}\omega = 0$. Here

$$T^1_{\text{Ad}}\omega(Y_i, Y_j) = \text{ad}(Y_i)\omega(Y_j) - \text{ad}(Y_j)\omega(Y_i).$$
Since $\omega$ is symmetric, one can choose the basis to be constituted of eigenvectors for $\omega$, i.e.
\[ \omega(Y_i) = \lambda_i Y_i. \]
Now $T^1_{\text{Ad}}\omega = 0$, implies that for all $i$ and $j$
\[ \lambda_j [Y_i, Y_j] = \lambda_i [Y_j, Y_i] \]
showing that, if $[Y_i, Y_j] \neq 0$, then $\lambda_i = -\lambda_j$. We shall use the following lemma

**Lemma 7.9.** — Let $\mathfrak{g}$ be a non compact simple Lie algebra and $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ a Cartan decomposition. Let $\{Y_1, \ldots, Y_n\}$ be a basis of $\mathfrak{p}$. Then for all $0 \leq r \leq n$ there exists $r_1, \ldots, r_k$, with $1 \leq r_i \leq n$ such that $r_1 = 1$, $r_k = r$ and $[Y_{r_i}, Y_{r_{i+1}}] \neq 0$ for all $1 \leq i \leq k - 1$.

It says that one can “reach” any $Y_r$ by a sequence of $Y_i$’s such that two successive $Y_i$’s do not commute. Here the simplicity of $G$ is essential.

This lemma implies that, for all $1 \leq i \leq n$,
\[ \lambda_i = \pm \lambda_1. \]

Let us study these eigenvalues and the corresponding eigenspaces. We let
\[ E = \{ Y \in \mathfrak{p} \mid \omega(Y) = \lambda_1 Y \} \]
\[ F = \{ Y \in \mathfrak{p} \mid \omega(Y) = -\lambda_1 Y \} \]

Then, since $\omega$ is symmetric
\[ \mathfrak{p} = E \bigoplus F. \]
$E$ is not reduced to $\{0\}$ since it contains at least $Y_1$, and $F$ is not trivial either thanks to the above lemma.

Now for $Y, Y' \in E$ (resp. $F$) one has $[Y, Y'] = 0$ otherwise the eigenvalues would have different signs.

If $Z \in \mathfrak{k}$, by symmetry of $\text{ad}(Y)$ we get that for all $Y, Y' \in E$ (resp. $F$)
\[ \langle [Z, Y], Y' \rangle = -\langle Z, [Y, Y'] \rangle = 0 \]
thus $\text{ad}(Z)(E) \subset E^\perp = F$ (resp. $\text{ad}(Z)(F) \subset E$). The endomorphism $\text{ad}(Z)\text{ad}(Z')$ then preserves $E$ and $F$ for $Z, Z' \in \mathfrak{k}$. We conclude that

$$\text{ad}([Z,Z'])(E) \subset \begin{cases} F & \text{since}[Z,Z'] \in \mathfrak{k} \\ E & \text{because of the above remark.} \end{cases}$$

which leads to

$$\text{ad}([Z,Z'])(E) = \text{ad}([Z,Z'])(F) = 0 \implies \text{ad}([Z,Z'])\bigg|_p = 0$$

that is the action of $\text{ad}(\mathfrak{k})$ on $\mathfrak{p}$ is abelian. On the other hand since $G$ is simple, this action is irreducible and faithful. Thus $\mathfrak{k}$ is abelian by the faithfulness and $\dim \mathfrak{p} = 1$ or 2 by the irreducibility. Moreover this action is skew-symmetric (i.e. $\text{ad}(Z)$ is skew-symmetric for all $Z \in \mathfrak{k}$).

Thus $\dim \mathfrak{p} = 2$ that is, in a suitable basis, for all $Z \in \mathfrak{k}$

$$\text{ad}(Z) = \begin{pmatrix} 0 & a \\ -a & 0 \end{pmatrix}, \ a \in \mathbb{R}, \ a > 0. \$$

The vector space $\{\text{ad}(Z) \mid Z \in \mathfrak{k}\}$ is then 1-dimensional and again by faithfulness, $\dim \mathfrak{b} = 1$. The Lie algebra $\mathfrak{g}$ is described as follows: Let $Z$ be a generator of $\mathfrak{k}$ and $Y_1$ and $Y_2$ a basis of $\mathfrak{p}$ in which $\text{ad}(Z)$ is written as above, then one has

$$[X,Y_1] = -aY_2, \ [X,Y_2] = aY_1 \text{ and } [Y_1,Y_2] = bX. \$$

Here $b \neq 0$ can be chosen positive ($\mathfrak{p}$ generates $\mathfrak{g}$ as a Lie algebra). Now by setting $X' = \frac{1}{a}X$ and $Y'_i = \frac{1}{\sqrt{ab}}Y_i$ we get the Lie algebra of $\text{SL}_2(\mathbb{R})$!

Thus for $\omega \neq 0$, $T^1_{\text{Ad}}(\omega) = 0$ if and only if $\mathfrak{g} = \mathfrak{sl}(2,\mathbb{R})$ and $\omega$ is a symmetric endomorphism with zero-trace (it has opposite eigenvalues).

It is not difficult to check that indeed in the case of $\mathfrak{sl}(2,\mathbb{R})$ such a $\omega$ gives $Q^1_{\text{ad}}(\omega) = 0$. The dimension of the kernel of $H^1_{\text{Ad}}$ is 1 in this case.

### 8. Extensions of this technique

This technique can be extended in various ways:

1. One can consider the non uniform case, then the Hodge theory works if one knows the existence of $L^2$-harmonic forms. This relies on the study of the structure of the cusps. Here one more case has to be excluded, this is the case when $G = \text{SL}_2(\mathbb{C})$, see [Ga].
2. This has been applied to the study of the rigidity of some hyperbolic metrics with conical singularities on a 3-manifold (see [K-H]). Here the problem reduces to the study of the Hodge theory with singularities.
